AB Organic electroluminescent devices are described which comprise a pair of electrodes sandwiching a light-emitting layer comprising a mixture of a hole-transporting material consisting of a tertiary amine compound, an electron-transporting material and a light-emitting additive material, in which the tertiary amine compound has ≥ 2 oxidation potentials differing by ≥ 0.22 V (determined by cyclic voltammetry) and a glass transition temperature of $\geq 100^\circ$, and the electron-transporting material has a glass transition temperature of $\geq 100^\circ$. Devices are described which entail employ specific tert. amine compds. Methods for fabricating the devices are also described.

AB The semiconductive polymers are useful for thin film electronic and optical
 devices, such as organic light emitting diodes (OLED) and photovoltaic
 devices, e.g. solar cells and photo detectors. The semiconductive polymers
 can be obtained by the Yamamoto or Suzuki polymerization method where increase
 of the number of nitrogen atoms in the backbone of repeat unit of a

semiconducting polymer improves its hole transporting capability. Appropriate selection of the polymerizable group of a monomer of a repeat unit enables the monomer to be polymerized by the Yamamoto or Suzuki polymerization which afford greater control over regioregularity of polymers as compared to prior art polymers.

AB The present invention relates to a device having a solid conjugated semiconductor comprising a hole transport material (HTM), in which the hole transport material is mixed with oxidized hole transport material as a dopant; to a mixture which can be used as doped hole transport material; and to methods for the preparation of devices having a solid conjugated semiconductor. The present invention also relates to a solar cell comprising such a device and to other devices made with conjugated semiconductors, such as diodes (LEDs), transistors etc.

AB The effect of annealing of organic thin films on charge injection in the tris(8-quinolinolato)aluminum (Alq3)-based organic electroluminescent (EL) devices was investigated. The external quantum and luminous efficiencies were found to improve by annealing. The investigation of the effect of annealing on charge injection in hole-only and electron-only devices has revealed that while hole injection from the ITO electrode into the hole-transport layer is not affected by the annealing, electron injection from the MgAg electrode into the Alq3 layer is enhanced by the annealing. It is concluded that improved charge balance due to the enhanced electron injection by the annealing is responsible for the improvement of the performance of the organic EL device.

AB A new family of hole-transporting amorphous mol. materials with high glass-transition temps. (Tg) were designed and synthesized. They include 4,4',4''-tris[biphenyl-2-yl(phenyl)amino]triphenylamine (o-PTDATA), 4,4',4''-tris[biphenyl-3-yl(phenyl)amino]triphenylamine (m-PTDATA), and 4,4',4''-tris[biphenyl-4-yl(3'-methylphenyl)amino]triphenylamine (p-PMTDATA). These compds. form readily stable amorphous glasses with high Tg and to function as materials for hole-injection layers in contact with the ITO electrode in multilayer organic light-emitting diodes (OLEDs). Such devices consisting of

double hole-transport layers of o-PTDATA or p-PMTDATA and N,N'-di(biphenyl-4-yl)-N,N'-diphenyl-[1,1'-biphenyl]-4,4'-diamine and the emitting layer of tris(8-quinolinolato)aluminum exhibit high performance and thermal stability. The devices operated at 150°, retaining a luminance of 80% of the initial value measured at 20°.

AB Polymers of formula I are provided which are incorporated in organic comps. for use as elec. and electronically active materials used in semiconductor devices such as organic light emitting diodes and photorefractive devices, wherein A, B, and C are independently selected from Ph and C1-8 alkyl, C1-8 alkoxy, or C1-8 dialkylamino-substituted Ph, n = 3-10,000. Thus poly(4-vinyltriphenylamine) was prepared by acylation of triphenylamine with acetyl chloride to give 4-acyltriphenylamine, followed by treating of 4-acyltriphenylamine with triisopropoxy aluminum to give monomer 4-vinyltriphenylamine, then purifying and free radical polymerization of the monomer, showing number average mol. weight 5460, weight average mol. weight 9940, and polydispersity index 1.82.

- AB A product obtained by Ullmann reaction of a first raw material with an excess of a second raw material which also serves as a high b.p. solvent for the reaction is purified by carrying out (1) a first liquid chromatog. using a first solvent as the mobile phase which exhibit insoly. or sparing solubility for the product but is capable of dissolving the unreacted second raw material, to completely elute out the excess second raw material and then (2) a second chromatog. using a second solvent as the mobile phase which is capable of dissolving the product to elute out the product. This chromatog. process removes the excess raw material with high boiling pt which is difficult to remove by distillation and thereby enables to purify a product at normal temperature without exposing it to high temperature and improves the quality and recovery ratio of the product. Thus, a THF extract of Ullmann reaction product containing N,N,N',N'-tetrakis(1-naphthyl)-1,1'-binaphthyl-3,3'-dimethyl-4,4'-diamine (I) (t-NPC) and 1-iodonaphthalene, which is obtained by reaction of N,N'-diphenylbenzidine with 2 equiv of 1-iodonaphthalene in the presence of Cu and K₂CO₃, was dissolved in a small amount of toluene to prepare a 50 mL sample solution. The sample solution was applied to a column of silica gel (400 g, 45 mm diameter + 700 mm length). The column was eluted using 2,000 mL hexane as the first mobile phase in which I is insol. or sparingly soluble, for eluting out 1-iodonaphthalene to sep. it from I also containing Ullmann reaction byproducts. The impurities of I containing the latter byproducts adsorbed on the column were dissolved in THF and isolated by distilling off THF. The column was then eluted at .apprx.140 drops/min using a mixed solvent of 3,00 mL toluene and 6,000 mL hexane as the second mobile phase which is a good solvent for I to isolate I in 70% recovery. I thus obtained possesses a good hole transport in electroluminescent device (no data).

ED  Entered STN:  08 Jun 1999
AB  Methods for preparing organic thin films on substrates are described which
    entail providing a plurality of organic precursors in the vapor phase, and
    reacting the plurality of organic precursors at a pressure below atmospheric
    pressure to produce a film on the substrate. The methods may be applied to
    the production of organic light-emitting devices. Apparatus for carrying out
    the methods is described which comprises a reaction chamber; means for heating
    the reaction chamber; means for introducing vapors of organic precursor
    materials into the reaction chamber; and means for reducing the pressure in
    the reaction chamber to below atmospheric pressure. Apparatus is also
    described which includes a plurality of vacuum chambers and a conveyor for
    moving substrates between them. Films, including light-emitting and nonlinear
    optical material films, formed by the methods are also claimed.

AB Compds. suitable for use in electroluminescent devices are described by such general formula as I (A= Q, Q1, Q2; Ar1-6 = independently selected (un)substituted aryl groups; X1-6 = independently selected O, S, C=O, SO2, Si(B1)B2, N(B1), PB1, P(:O)B1-, -(CH2)x-O-(CH2)y-, (un)substituted alkylene groups, or (un)substituted alicyclic moieties; B1 and B2 = independently selected (un)substituted alkyl group or a (un)substituted aryl group), etc. The materials may be hole-injecting materials. Devices using the materials, including display devices, are also described, as is the use of the materials in the devices.

AB The novel organic hyperbranched π -electron systems, 1,3,5-tris[N-(4'-methylbiphenyl-4-yl)-N-(4-diphenylaminophenyl)amino]benzene (TDAB-G1(a)) and 1,3,5-tris[N-[4-bis(4-methylphenyl)aminophenyl]-N-(4-diphenylaminophenyl)amino]benzene (TDAB-G1(b)), were synthesized via the Ullmann reaction and characterized by ¹H-, ¹³C-NMR, electron absorption spectroscopy, and elemental anal. TDAB-G1(a) was obtained as a polycryst. material, whereas TDAB-G1(b) was an amorphous glass. DSC anal. of TDAB-G1(a) gave a m.p. of 187°. When the melted sample was cooled in air, a glass was formed spontaneously. Reheating of the glass sample resulted in a glass transition at T_g = 128° giving a supercooled liquid. Likewise, the amorphous repptd. sample of TDAB-G1(b) exhibited a glass transition at T_g = 134° when heated. Unique multiredox processes involving as many as 6- and 9-electron reversible oxidns. were observed in the cyclic voltammograms of TDAB-G1(a) and TDAB-G1(b), resp. TDAB-G1(b) was used as a hole-transport material in a multilayer organic LED consisting of the double-hole transport layer and an emitting layer which contained N,N'-diphenyl-N,N'-bis(3-methylphenyl)-[1,1'-biphenyl]-4,4'-diamine (TPD) doped with rubrene as the emitting material and with tris(8-quinolinolato) Al as the electron transport material. This device emitted yellow light and the electroluminescence showed a peak at 560 nm in agreement with the luminescence peak of rubrene.

AB For the purpose of developing an amorphous mol. material with a high glass transition temperature (Tg) and a low ionization potential for use as a charge-transport layer in organic electroluminescent (EL) devices, a novel starburst mol., 4,4',4''-tris[bis(4'-tert-butylbiphenyl-4-yl)amino]triphenylamine (t-Bu-TBATA), was designed and synthesized. T-Bu-TBATA was found to form readily a stable glass with a Tg of 203°. A multilayer EL device consisting of double hole transport layers of t-Bu-TBATA and 4,4',4''-tri(N-carbazolyl)triphenylamine and an emitting layer of tris(8-quinolinolato) Al was fabricated and its performances were examined. The device was found to exhibit good performances and to be thermally stable, operating even at 170°.

AB The polyarylpolyamines are prepared by the reaction of ≥ 1 tertiary di- or polyarylamine having 2 halogen substituents with a haloarom. compound having a crosslinkable reactive group or trialkylsiloxy moiety. Films of the title compds., as well as films of polymers of their crosslinkable species, are efficient in the transport of pos. charges when exposed to relatively low voltage levels, and demonstrate solvent and heat resistance.

AB Hole-transporting materials comprise triaryl amines described by the general formula I (R1-6 = (un)substituted aryl groups; and Ar1-3 = (un)substituted arylene groups, with the restriction that ≥1 of R1-6 = comprises fused aromatic rings or is an aryl group having a cycloalkyl ring). Organic electroluminescent devices and electrophotog. photoreceptors employing the materials are also described.

AB The synthesis, morphol., and solid-state properties of the novel starburst mol. 1,3,5-tris[N-(4-diphenylaminophenyl)phenylamino]benzene (I) are described. UV-, phosphorescence, and fluorescence spectra of I are red-shifted relative to 1,3,5-tris[(4-diphenylaminophenyl)amino]benzene. The compound I readily forms a stable amorphous glass in relation to a glass-transition temperature of 108° when cooled from a melt. The ratio of

photocurrent to dark current of the amorphous I film (thickness 0.18 μm) was .apprx.200 at elec. field of $2 + 105 \text{ V-cm}^{-1}$ under exposure with 365 nm at 5.4 mW-cm^{-2} . The films of I function as a photoactive pn heterojunction-type photovoltaic devices, and a charge-transport material for electroluminescent devices.
